CryptoAuthLib - Microchip CryptoAuthentication Library

Introduction

This library implements the APIs required to communicate with Microchip Security device. The family of devices supported currently are:

- [ATSHA204A](#)
- [ATECC108A](#)
- [ATECC508A](#)
- [ATECC608A](#)
- [ATECC608B](#)

The best place to start is with the [Microchip Trust Platform](#)

Online API documentation is at <https://microchiptech.github.io/cryptoauthlib/>

Latest software and examples can be found at:

- <https://www.microchip.com/design-centers/security-ics/trust-platform>
- <http://www.microchip.com/SWLibraryWeb/product.aspx?product=CryptoAuthLib>

Prerequisite hardware to run CryptoAuthLib examples:

- [CryptoAuth Trust Platform Development Kit](#)

Alternatively a Microchip MCU and Adapter Board:

- [ATSAMR21 Xplained Pro](#) or [ATSAMD21 Xplained Pro](#)
- [CryptoAuth Xplained Pro Extension Board](#) or [CryptoAuthentication SOIC Socket Board](#) to accept SOIC parts

For most development, using socketed top-boards is preferable until your configuration is well tested, then you can commit it to a CryptoAuth Xplained Pro Extension, for example. Keep in mind that once you lock a device, it will not be changeable.

Examples

- Watch [CryptoAuthLib Documents](#) for new examples coming online.
- Node Authentication Example Using Asymmetric PKI is a complete, all-in-one example demonstrating all the stages of crypto authentication starting from provisioning the Crypto Authentication device ATECC608/ATECC508A with keys and certificates to demonstrating an authentication sequence using asymmetric techniques. <http://www.microchip.com/SWLibraryWeb/product.aspx?product=CryptoAuthLib>

Configuration

In order to properly configured the library there must be a header file in your project named `atca_config.h` at minimum this needs to contain defines for the hal and device types being used. Most integrations have an configuration mechanism for generating this file. See the [atca_config.h.in](#) template which is configured by CMake for Linux, MacOS, & Windows projects.

An example of the configuration:

```
/* Cryptoauthlib Configuration File */
#ifndef ATCA_CONFIG_H
#define ATCA_CONFIG_H
/* Include HALS */
#define ATCA_HAL_I2C
/* Included device support */
#define ATCA_ATECC608_SUPPORT
/* \brief How long to wait after an initial wake failure for the POST to
 *      complete.
 * If Power-on self test (POST) is enabled, the self test will run on waking
 * from sleep or during power-on, which delays the wake reply.
 */
#ifndef ATCA_POST_DELAY_MSEC
#define ATCA_POST_DELAY_MSEC 25
#endif
#endif // ATCA_CONFIG_H
```

There are two major compiler defines that affect the operation of the library.

- `ATCA_NO_POLL` can be used to revert to a non-polling mechanism for device responses. Normally responses are polled for after sending a command, giving quicker response times. However, if `ATCA_NO_POLL` is defined, then the library will simply delay the max execution time of a command before reading the response.
- `ATCA_NO_HEAP` can be used to remove the use of malloc/free from the main library. This can be helpful for smaller MCUs that don't have a heap implemented. If just using the basic API, then there shouldn't be any code changes required. The lower-level API will no longer use the new/delete functions and the init/release functions should be used directly.

Host Device Support

CryptoAuthLib will run on a variety of platforms from small micro-controllers to desktop host systems. The current list of hardware abstraction layer support includes:

Rich OS Hosts:

- Linux Kit Protocol over HID USB
- Linux I2C
- Linux SPI
- Windows Kit Protocol over HID USB

Microcontrollers:

- Microchip AVR, SAM, & PIC families. See hal readme

If you have specific microcontrollers or Rich OS platforms you need support for, please contact us through the Microchip portal with your request.

CryptoAuthLib Architecture

Cryptoauthlib API documentation is at <https://microchiptech.github.io/cryptoauthlib/>

The library is structured to support portability to:

- multiple hardware/microcontroller platforms
- multiple environments including bare-metal, RTOS and Windows/Linux/macOS
- multiple chip communication protocols (I2C, SPI, and SWI)

All platform dependencies are contained within the HAL (hardware abstraction layer).

Directory Structure

```
lib - primary library source code
lib/atcacert - certificate data and i/o methods
lib/calib - the Basic Cryptoauth API
lib/crypto - Software crypto implementations external crypto libraries support (primarily SHA1 and SHA256)
lib/hal - hardware abstraction layer code for supporting specific platforms
lib/host - support functions for common host-side calculations
lib/jwt - json web token functions
test - Integration test and examples. See test/cmd-processor.c for main() implementation.
For production code, test directories should be excluded by not compiling it
into a project, so it is up to the developer to include or not as needed. Test
code adds significant bulk to an application - it's not intended to be included
in production code.
```

Tests

There is a set of integration tests found in the test directory which will at least partially demonstrate the use of the objects. Some tests may depend upon a certain device being configured in a certain way and may not work for all devices or specific configurations of the device.

The test/cmd-processor.c file contains a main() function for running the tests. It implements a command-line interface. Typing help will bring up the list of commands available.

One first selects a device type, with one of the following commands:

- 204 (ATSHA204A)
- 108 (ATECC108A)
- 508 (ATECC508A)
- 608 (ATECC608A/B)

From there the following unit test sweets are available:

- unit (test command builder functions)
- basic (test basic API functions)
- cio (test certification i/o functions)
- cd (test certificate data functions)
- util (test utility functions)
- crypto (test software crypto functions)

Tests available depend on the lock level of the device. The unit tests won't lock the config or data zones automatically to allow retesting at desired lock levels. Therefore, some commands will need to be repeated after locking to exercise all available tests.

Starting from a blank device, the sequence of commands to exercise all unit tests is:

```
unit
basic
lockcfg
unit
basic
lockdata
unit
basic
cio
cd
util
crypto
```

Using CryptoAuthLib (Microchip CryptoAuth Library)

The best place to start is with the [Microchip Trust Platform](#)

Also application examples are included as part of the Harmony 3 framework and can be copied from the Harmony Content Manager or found with the Harmony 3 Framework [Cryptoauthlib_apps](#)

Incorporating CryptoAuthLib in a Linux project using USB HID devices

The Linux HID HAL files use the Linux udev development software package.

To install the udev development package under Ubuntu Linux, please type the following command at the terminal window:

```
sudo apt-get install libudev-dev
```

This adds the udev development development software package to the Ubuntu Linux installation.

The Linux HID HAL files also require a udev rule to be added to change the permissions of the USB HID Devices. Please add a new udev rule for the Microchip CryptoAuth USB devices.

```
cd /etc/udev/rules.d
sudo touch mchp-cryptoauth.rules
```

Edit the mchp-cryptoauth.rules file and add the following line to the file:

```
SUBSYSTEM=="hidraw", ATTRS{idVendor}=="03eb", ATTRS{idProduct}=="2312", MODE="0666"
```

openssl directory - Purpose

This directory contains the interfacing and wrapper functions to integrate openssl as the software crypto library.

Chapter 4

Application Support

This directory is for application specific implementation of various use cases.

Methods in this directory provide a simple API to perform potentially complex combinations of calls to the main library or API.

[IP Protection with Symmetric Authentication](#)

[PKCS11 Application Information](#)

[Secure boot using ATECC608](#)

4.1 IP Protection with Symmetric Authentication

The IP protection can be easily integrated to the existing projects. The user project should include [symmetric_authentication.c](#) & [symmetric_authentication.h](#) files which contains the api

- [symmetric_authenticate\(\)](#) - For Performing the authentication between host & device.

User Considerations

- The user should take care on how the master key should be stored on the MCU side.
- The api's in the file doesn't do the provisioning of the chip and user should take care of the provisioning.

With the provisioned cryptoauthentication device and after doing the cryptoauthlib initialisation, user should only be calling the function [symmetric_authenticate\(\)](#) with its necessary parameters for the authentication. The returned authentication status should be used in the application.

Examples

4.2 PKCS11 Application Information

Setting up cryptoauthlib as a PKCS11 Provider for your system (LINUX)

These instructions are for building, installing and configuring cryptoauthlib as a pkcs11 provider. These instructions are for commonly available Linux systems with package managers.

Update libp11 on the system. The version should be at minimum 0.4.10

- Install the build dependencies for the system:

```
```bash
```

#### Debian like systems

```
$ sudo apt-get build-dep libengine-pkcs11-openssl1.1 ```
```

```
```bash
```

RPM based systems

```
$ yum-builddep engine-pkcs11 ```
```

- Change to a sane directory

```
```bash cd ~ ```
```

- Get the latest version of libp11

```
```bash $ git clone https://github.com/OpenSC/libp11.git ```
```

- Rerun the build configuration tools:

```
``` $ cd libp11 $ ./bootstrap $ ./configure ```
```

- Build the library:

```
```bash $ make ```
```

- Install the library:

```
```bash $ sudo make install ```
```

#### Build and Install cryptoauthlib with PKCS11 support

- Install the build dependencies for the system:

```
```bash
```

Debian like systems

```
$ sudo apt-get install cmake libudev-dev ```
```

```
```bash
```

### RPM based systems

```
$ yum install cmake $ yum install libudev-devel ``
```

- Change to a sane directory

```
``bash cd ~ ``
```

- Get the latest version of cryptoauthlib with PKCS11 support

```
``bash $ git clone --single-branch -b pkcs11 https://github.com/MicrochipTech/cryptoauthlib ``
```

- Rerun the build configuration tools:

```
``bash $ cd cryptoauthlib $ cmake . ``
```

- Build the library:

```
``bash $ make ``
```

- Install the library:

```
``bash $ sudo make install ``
```

### Configuring the cryptoauthlib PKCS11 library

By default the following files will be created.

- /etc/cryptoauthlib/cryptoauthlib.conf

```
``text
```

### Cryptoauthlib Configuration File

```
filestore = /var/lib/cryptoauthlib ``
```

- /var/lib/cryptoauthlib/slot.conf.tmpl

```
``text
```

### Reserved Configuration for a device

**The objects in this file will be created and marked as undeletable**

**These are processed in order. Configuration parameters must be comma**

**delimited and may not contain spaces**

```
interface = i2c,0xB0 freeslots = 1,2,3
```

### Slot 0 is the primary private key

```
object = private,device,0
```

## Slot 10 is the certificate data for the device's public key

```
#object = certificate,device,10
```

## Slot 12 is the intermediate/signer certificate data

```
#object = certificate,signer,12
```

## Slot 15 is a public key

```
object = public,root,15 ``
```

### cryptoauthlib.conf

This file provides the basic configuration information for the library. The only variable is "filestore" which is where cryptoauthlib will find device specific configuration and where it will store object files from pkcs11 operations.

### slot.conf.tmpl

This is a template for device configuration files that cryptoauthlib will use to map devices and their resources into pkcs11 tokens and objects.

A device file must be named <pkcs11\_slot\_number>.conf

For a single device:

```
$ cd /var/lib/cryptoauthlib
$ cp slot.conf.tmpl 0.conf
```

Then edit 0.conf to match the device configuration being used.

**interface** Allows values: 'hid', 'i2c' If using i2c specify the address in hex for the device. This is in the device format (upper 7 bits define the address) so will not appear the same as the i2cdetect address (lower 7 bits)

**freeslots** This is a list of slots that may be used by the library when a pkcs11 operation that creates new objects is used. When the library is initialized it will scan for files of the form <pkcs11\_slot\_num>.<device\_slot\_num>.conf which defines the object using that device resource.

## Using p11-kit-proxy

This is an optional step but is very helpful for using multiple pkcs11 libraries in a system. Detailed setup can be found at [p11-glue](#)

```
Debian like systems
$ sudo apt-get install p11-kit
RPM based systems
$ yum install p11-kit
```

- Create or edit the global configuration file /etc/pkcs11/pkcs11.conf. The directory /etc/pkcs11 may require creation first.

```
``
```

**This setting controls whether to load user configuration from the**

**`~/.config/pkcs11` directory. Possible values:**

**none: No user configuration**

**merge: Merge the user config over the system configuration (default)**

**only: Only user configuration, ignore system configuration**

`user-config: merge ```

- Create a module configuration file.
  - User module name (only available for a single user): `~/.config/pkcs11/modules/cryptoauthlib.↵  
module`
  - Global module name (available to the whole system): `/usr/share/p11-kit/modules/cryptoauthlib.modu  
`` module: /usr/lib/libcryptoauth.so critical: yes trust-policy: yes managed: yes log-calls: no ```

For more details on the configuration files see the [configuration documentation](#).

## Without using p11-kit-proxy

OpenSSL (via the libp11 project above) and p11tool support p11-kit-proxy natively so do not require additional set up if it is being used. If p11-kit-proxy is not being used then OpenSSL will have to be manually configured to use libp11 and cryptoauthlib

This requires editing the default openssl.cnf file. To locate the file being used by the system run the following command:

```
$ openssl version -a | grep OPENSSLDIR:
OPENSSLDIR: "/usr/lib/ssl"
```

This gives the default path where openssl is compiled to find the openssl.cnf file

In this case the file to edit will be `/usr/lib/ssl/openssl.cnf`

This line must be placed at the top, before any sections are defined:

```
openssl_conf = openssl_init
```

This should be added to the bottom of the file:

```
[openssl_init]
engines=engine_section
[engine_section]
pkcs11 = pkcs11_section
[pkcs11_section]
engine_id = pkcs11
Wherever the engine installed by libp11 is. For example it could be:
/usr/lib/arm-linux-gnueabi/hf/engines-1.1/libpkcs11.so
dynamic_path = /usr/lib/ssl/engines/libpkcs11.so
MODULE_PATH = /usr/lib/libcryptoauth.so
init = 0
```

## Testing

To use p11tool it has to be installed:

```
Debian like systems
$ sudo apt-get install gnutls-bin
RPM based systems
$ yum install gnutls-utils
```

**Note:** If not using p11-kit-proxy then the provider has to be specified in p11tool calls:

```
$ p11tool --provider=/usr/lib/libcryptoauth.so
```

- Get the public key for a private key (as defined by the 0.conf file cited above):

```
```bash $ p11tool --export-pubkey "pkcs11:token=0123EE;object=device;type=private" warning: --login was
not specified and it may be required for this operation. warning: no --outfile was specified and the public
key will be printed on screen. -----BEGIN PUBLIC KEY----- MFkwEwYHKoZIzj0CAQYIKoZIzj0DAQcDQg

```

- Get the public key and decode it using OpenSSL

```
```bash $ p11tool --export-pubkey "pkcs11:token=0123EE;object=device;type=private" | openssl pkey -pubin
-text -noout warning: --login was not specified and it may be required for this operation. warning: no --outfile

- Create a CSR for the private key

## 4.3 Secure boot using ATECC608

The SecureBoot command is a new feature on the [ATECC608A](#) device compared to earlier CryptoAuthentication devices from Microchip. This feature helps the MCU to identify fraudulent code installed on it. When this feature is implemented, the MCU can send a firmware digest and signature to the ATECC608. The ATECC608 validates this information (ECDSA verify) and responds to host with a yes or no answer.

The ATECC608 provides options to reduce the firmware verification time by storing the signature or digest after a good full verification (FullStore mode of the SecureBoot command).

### 4.3 Secure boot using ATECC608

---

- When the ATECC608 stores the digest (SecureBootMode is FullDig), the host only needs to send the firmware digest, which is compared to the stored copy. This skips the comparatively lengthy ECDSA verify, speeding up the secure boot process.
- When the ATECC608 stores the signature (SecureBootMode is FullSig), the host only needs to send the firmware digest, which is verified against the stored signature using ECDSA. This saves time by not needing to send the signature in the command over the bus.

The ATECC608 also provides wire protection features for the SecureBoot command, which can be used to encrypt the digest being sent from the host to the ATECC608 and add a MAC to the verify result coming back to the host so it can't be forced to a success state. This feature makes use of a shared secret between the host and ATECC608, called the IO protection key.

The secure boot feature can be easily integrated to an existing project. The project should include the following files from the `secure_boot` folder:

- [secure\\_boot.c](#)
- [secure\\_boot.h](#)
- [secure\\_boot\\_memory.h](#)
- [io\\_protection\\_key.h](#)

The project should also implement the following platform-specific APIs:

- [secure\\_boot\\_init\\_memory\(\)](#)
- [secure\\_boot\\_read\\_memory\(\)](#)
- [secure\\_boot\\_deinit\\_memory\(\)](#)
- [secure\\_boot\\_mark\\_full\\_copy\\_completion\(\)](#)
- [secure\\_boot\\_check\\_full\\_copy\\_completion\(\)](#)
- [io\\_protection\\_get\\_key\(\)](#)
- [io\\_protection\\_set\\_key\(\)](#)

The project can set the secure boot configuration with the following defines:

- `SECURE_BOOT_CONFIGURATION`
- `SECURE_BOOT_DIGEST_ENCRYPT_ENABLED`
- `SECURE_BOOT_UPGRADE_SUPPORT`

The secure boot process is performed by initializing CryptoAuthLib and calling the [secure\\_boot\\_process\(\)](#) function.

## Implementation Considerations

- Need to perform SHA256 calculations on the host. CryptoAuthLib provides a software implementation in [lib/crypto/atca\\_crypto\\_sw\\_sha2.c](#)
- When using the wire protection features:
  - The host needs to be able to generate a nonce (number used once). This is the NumIn parameter to the Nonce command that is sent before the SecureBoot command. The ATECC608 can not be used to generate NumIn, but it should come from a good random or non-repeating source in the host.
  - If the host has any protected internal memory, it should be used to store its copy of the IO protection key.
- Secure boot depends on proper protections of the boot loader code in the host. If the code can be easily changed, then the secure boot process can be easily skipped. Boot loader should ideally be stored in an immutable (unchangeable) location like a boot ROM or write-protected flash.
- Note that these APIs don't provision the ATECC608. They assume the ATECC608 has already been configured and provisioned with the necessary keys for secure boot.

## Examples

For more information about secure boot, please see the example implementation project and documentation at: [https://github.com/MicrochipTech/cryptoauth\\_usecase\\_secureboot](https://github.com/MicrochipTech/cryptoauth_usecase_secureboot)

### 8.1 Basic Crypto API methods (atcab\_)

These methods provide the most convenient, simple API to CryptoAuth chips.

#### Macros

- `#define atcab_get_addr(...) calib_get_addr(__VA_ARGS__)`
- `#define atca_execute_command(...) calib_execute_command(__VA_ARGS__)`
- `#define SHA_CONTEXT_MAX_SIZE (109)`

#### Functions

- `ATCA_STATUS atcab_version (char *ver_str)`  
*basic API methods are all prefixed with atcab\_ (CryptoAuthLib Basic) the fundamental premise of the basic API is it is based on a single interface instance and that instance is global, so all basic API commands assume that one global device is the one to operate on.*

Verify a client's response to a challenge using software crypto functions. The function is currently not implemented.

The challenge-response protocol is an ECDSA Sign and Verify. This performs an ECDSA verify on the response returned by the client, verifying the client has the private key counter-part to the public key returned in its certificate.

### Parameters

in	<i>device_public_key</i>	Device public key as read from its certificate. Formatted as the X and Y integers concatenated together. 64 bytes.
in	<i>challenge</i>	Challenge that was sent to the client. 32 bytes.
in	<i>response</i>	Response returned from the client to be verified. 64 bytes.

Returns

ATCA\_UNIMPLEMENTED , as the function is currently not implemented.

```
int atcacert_write_cert (
 const atcacert_def_t * cert_def,
 const uint8_t * cert,
 size_t cert_size)
```

Take a full certificate and write it to the ATECC508A device according to the certificate definition.

Parameters

in	<i>cert_def</i>	Certificate definition describing where the dynamic certificate information is and how to store it on the device.
in	<i>cert</i>	Full certificate to be stored.
in	<i>cert_size</i>	Size of the full certificate in bytes.

Returns

ATCACERT\_E\_SUCCESS on success, otherwise an error code.

## 8.6 Basic Crypto API methods for CryptoAuth Devices (calib\_)

These methods provide a simple API to CryptoAuth chips.

### 8.6.0.1 calib directory - Purpose

The purpose of this directory is to contain the files implementing the APIs for a basic interface to the core CryptoAuthLib library.

High-level functions like these make it very convenient to use the library when standard configurations and defaults are in play. They are the easiest to use when developing examples or trying to understand the "flow" of an authentication operation without getting overwhelmed by the details.

This makes simple jobs easy and if you need more sophistication and power, you can employ the full power of the CryptoAuthLib object model.

See the Doxygen documentation in `cryptoauthlib/docs` for details on the API of the calib commands.

## 8.8 Hardware abstraction layer (hal\_)

These methods define the hardware abstraction layer for communicating with a CryptoAuth device.

### 8.8.0.1 HAL Directory - Purpose

This directory contains all the Hardware Abstraction Layer (HAL) files used to adapt the upper levels of atca-ng and abstractions to physical hardware.

HAL contains physical implementations for I2C, SWI, SPI, UART and timers for specific hardware platforms.

**Include just those HAL files you require based on platform type.**

## Cryptoauthlib HAL Architecture

Cryptoauthlib has several intermediate conceptual layers

1. The highest layer of cryptoauthlib (outside of integration APIS) that may be used with an application is the `atcab_api` functions. These are general purpose functions that present a simple and consistent crypto interface to the application regardless of the device being used.
2. `calib_`, `talib_` APIs are the library functions behind `atcab_` ones that generate the correct command packets and process the received responses. Device specific logic is handled by the library here
3. `hal_` these functions perform the transmit/recieve of data for a given interface. These are split into sublayers
  - The HAL layer is the first hal layer that presents the interface expected by the higher level library. When using a native driver and no further interpretation is required this layer is all that is required.
  - The PHY layer if for hals that perform an interpretation or additional protocol logic. In this situation the HAL performs protocol interpretation while the phy performs the physical communication

**HAL and PHY Requirements** The hal and phy layers have the same construction. A hal or phy must have the following functions and their signatures

- `ATCA_STATUS hal_<name>init(ATCAIface iface, ATCAIfaceCfg *cfg);`
- `ATCA_STATUS hal_<name>post_init(ATCAIface iface);`
- `ATCA_STATUS hal_<name>send(ATCAIface iface, uint8_t address, uint8_t *txdata, int txlength);`
- `ATCA_STATUS hal_<name>receive(ATCAIface iface, uint8_t address, uint8_t *rxdata, uint16_t *rxlength);`
- `ATCA_STATUS hal_<name>control(ATCAIface iface, uint8_t option, void* param, size_t paramlen);`
- `ATCA_STATUS hal_<name>_release(void *hal_data);`

If the hal is a native driver no phy is required. See the tables below for which hal is required to be ported based on a configured interface

## 8.9 Host side crypto methods (atcah\_)

Use these functions if your system does not use an ATCADevice as a host but implements the host in firmware. The functions provide host-side cryptographic functionality for an ATECC client device. They are intended to accompany the CryptoAuthLib functions. They can be called directly from an application, or integrated into an API.

### 8.9.1 Detailed Description

Use these functions if your system does not use an ATCADevice as a host but implements the host in firmware. The functions provide host-side cryptographic functionality for an ATECC client device. They are intended to accompany the CryptoAuthLib functions. They can be called directly from an application, or integrated into an API.

Modern compilers can garbage-collect unused functions. If your compiler does not support this feature, you can just discard this module from your project if you do use an ATECC as a host. Or, if you don't, delete the functions you do not use.

8.9.4 Function Documentation

8.9.4.1 atcah\_check\_mac()

```
ATCA_STATUS atcah_check_mac (
 struct atca_check_mac_in_out * param)
```

This function performs the checkmac operation to generate client response on the host side .

Parameters

in, out	param	Input and output parameters
---------	-------	-----------------------------

Returns

ATCA\_SUCCESS on success, otherwise an error code.

8.9.4.2 atcah\_config\_to\_sign\_internal()

```
ATCA_STATUS atcah_config_to_sign_internal (
 ATCADeviceType device_type,
 struct atca_sign_internal_in_out * param,
 const uint8_t * config)
```

Populate the slot\_config, key\_config, and is\_slot\_locked fields in the [atca\\_sign\\_internal\\_in\\_out](#) structure from the provided config zone.

The [atca\\_sign\\_internal\\_in\\_out](#) structure has a number of fields (slot\_config, key\_config, is\_slot\_locked) that can be determined automatically from the current state of TempKey and the full config zone.

Parameters

in, out	param	Sign(Internal) parameters to be filled out. Only slot_config, key_config, and is_slot_locked will be set.
in	device_type	The type of the device.
in	config	Full 128 byte config zone for the device.

### Returns

ATCA\_SUCCESS on success, otherwise an error code.

#### 8.9.4.3 atcah\_decrypt()

```
ATCA_STATUS atcah_decrypt (
 struct atca_decrypt_in_out * param)
```

This function decrypts 32-byte encrypted data received with the Read command.

To use this function, first the nonce must be valid and synchronized between device and application. The application sends a GenDig command to the Device, using a key specified by SlotConfig.ReadKey. The device updates its TempKey. The application then updates its own TempKey using the GenDig calculation function, using the same key. The application sends a Read command to the device for a user zone configured with EncryptRead. The device encrypts 32-byte zone content, and outputs it to the host. The application passes these encrypted data to this decryption function. The function decrypts the data and returns them. TempKey must be updated by GenDig using a ParentKey as specified by SlotConfig.ReadKey before executing this function. The decryption function does not check whether the TempKey has been generated by a correct ParentKey for the corresponding zone. Therefore to get a correct result, the application has to make sure that prior GenDig calculation was done using correct ParentKey.

### Parameters

in, out	param	pointer to parameter structure
---------	-------	--------------------------------

### Returns

ATCA\_SUCCESS on success, otherwise an error code.

#### 8.9.4.4 atcah\_derive\_key()

```
ATCA_STATUS atcah_derive_key (
 struct atca_derive_key_in_out * param)
```

This function derives a key with a key and TempKey.

Used in conjunction with DeriveKey command, the key derived by this function will match the key in the device. Two kinds of operation are supported:

- Roll Key operation: target\_key and parent\_key parameters should be set to point to the same location (TargetKey).

```
CK_RV pkcs11_attrib_fill (
 CK_ATTRIBUTE_PTR pAttribute,
 const CK_VOID_PTR pData,
 const CK_ULONG ulSize)
```

Perform the nessasary checks and copy data into an attribute structure.

The ulValueLen field is modified to hold the exact length of the specified attribute for the object. In the special case of an attribute whose value is an array of attributes, for example CKA\_WRAP\_TEMPLATE, where it is passed in with pValue not NULL, then if the pValue of elements within the array is NULL\_PTR then the ulValueLen of elements within the array will be set to the required length. If the pValue of elements within the array is not NULL\_PTR, then the ulValueLen element of attributes within the array MUST reflect the space that the corresponding pValue points to, and pValue is filled in if there is sufficient room. Therefore it is important to initialize the contents of a buffer before calling C\_GetAttributeValue to get such an array value. If any ulValueLen within the array isn't large enough, it will be set to CK\_UNAVAILABLE\_INFORMATION and the function will return CKR\_BUFFER\_TOO\_SMALL, as it does if an attribute in the pTemplate argument has ulValueLen too small. Note that any attribute whose value is an array of attributes is identifiable by virtue of the attribute type having the CKF\_ARRAY\_ATTRIBUTE bit set.

## 8.13 TNG API (tng\_)

These methods provide some convenience functions (mostly around certificates) for TNG devices, which currently include ATECC608A-MAHTN-T.

### 8.13.0.1 TNG Functions

This folder has a number of convenience functions for working with TNG devices (currently ATECC608A-MAHTN-T).

These devices have standard certificates that can be easily read using the functions in [tng\\_atcacert\\_client.h](#)

### Functions

- const [atcacert\\_def\\_t \\* tng\\_map\\_get\\_device\\_cert\\_def](#) (int index)  
*Helper function to iterate through all trust cert definitions.*
- [ATCA\\_STATUS tng\\_get\\_device\\_cert\\_def](#) (const [atcacert\\_def\\_t \\*\\*cert\\_def](#))  
*Get the TNG device certificate definition.*
- [ATCA\\_STATUS tng\\_get\\_device\\_pubkey](#) (uint8\_t \*public\_key)

8.13.3 Function Documentation

8.13.3.1 tng\_atcacert\_device\_public\_key()

```
int tng_atcacert_device_public_key (
 uint8_t * public_key,
 uint8_t * cert)
```

Reads the device public key.

Parameters

out	<i>public_key</i>	Public key will be returned here. Format will be the X and Y integers in big-endian format. 64 bytes for P256 curve.
in	<i>cert</i>	If supplied, the device public key is used from this certificate. If set to NULL, the device public key is read from the device.

Returns

ATCACERT\_E\_SUCCESS on success, otherwise an error code.

8.13.3.2 tng\_atcacert\_max\_device\_cert\_size()

```
int tng_atcacert_max_device_cert_size (
 size_t * max_cert_size)
```

Return the maximum possible certificate size in bytes for a TNG device certificate. Certificate can be variable size, so this gives an appropriate buffer size when reading the certificate.

## 8.13 TNG API (tng\_)

---

### Parameters

out	<i>max_cert_size</i>	Maximum certificate size will be returned here in bytes.
-----	----------------------	----------------------------------------------------------

### Returns

#### 8.13.3.3 tng\_atcacert\_max\_signer\_cert\_size()

```
int tng_atcacert_max_signer_cert_size (
 size_t * max_cert_size)
```

Return the maximum possible certificate size in bytes for a TNG signer certificate. Certificate can be variable size, so this gives an appropriate buffer size when reading the certificate.

### Parameters

out	<i>max_cert_size</i>	Maximum certificate size will be returned here in bytes.
-----	----------------------	----------------------------------------------------------

### Returns

ATCACERT\_E\_SUCCESS on success, otherwise an error code.

#### 8.13.3.4 tng\_atcacert\_read\_device\_cert()

```
int tng_atcacert_read_device_cert (
 uint8_t * cert,
 size_t * cert_size,
 const uint8_t * signer_cert)
```

Reads the device certificate for a TNG device.

### Parameters

out	<i>cert</i>	Buffer to received the certificate (DER format).
in, out	<i>cert_size</i>	As input, the size of the cert buffer in bytes. As output, the size of the certificate returned in cert in bytes.
in	<i>signer_cert</i>	If supplied, the signer public key is used from this certificate. If set to NULL, the signer public key is read from the device.

### Returns

ATCACERT\_E\_SUCCESS on success, otherwise an error code.

### 8.13.3.5 tng\_atcacert\_read\_signer\_cert()

```
int tng_atcacert_read_signer_cert (

```

Reads the signer certificate for a TNG device.

#### Parameters

out	<i>cert</i>	Buffer to received the certificate (DER format).
in, out	<i>cert_size</i>	As input, the size of the cert buffer in bytes. As output, the size of the certificate returned in cert in bytes.

#### Returns

### 10.56.1 Detailed Description

Declarations for certificates related to ECC CryptoAuthentication devices. These are the definitions required to define a certificate and its various elements with regards to the CryptoAuthentication ECC devices.

Only the dynamic elements of a certificate (the parts of the certificate that change from device to device) are stored on the ATECC device. The definitions here describe the form of the certificate, and where the dynamic elements can be found both on the ATECC device itself and in the certificate template.

This also defines utility functions for working with the certificates and their definitions.

### 10.71.1 Detailed Description

Microchip CryptoAuthentication device command builder - this is the main object that builds the command byte strings for the given device. It does not execute the command. The basic flow is to call a command method to build the command you want given the parameters and then send that byte string through the device interface.

The primary goal of the command builder is to wrap the given parameters with the correct packet size and CRC. The caller should first fill in the parameters required in the [ATCAPacket](#) parameter given to the command. The command builder will deal with the mechanics of creating a valid packet using the parameter information.

### 10.72.1 Detailed Description

Microchip Crypto Auth device command object - this is a command builder only, it does not send the command. The result of a command method is a fully formed packet, ready to send to the ATCAIFace object to dispatch.

This command object supports the ATSHA and ATECC device family. The command list is a superset of all device commands for this family. The command object differentiates the packet contents based on specific device type within the family.

### 10.76.1 Detailed Description

Implements an execution handler that executes a given command on a device and returns the results.

This implementation wraps Polling and No polling (simple wait) schemes into a single method and use it across the library. Polling is used by default, however, by defining the ATCA\_NO\_POLL symbol the code will instead wait an estimated max execution time before requesting the result.

### 10.77.1 Detailed Description

Defines an execution handler that executes a given command on a device and returns the results.

The basic flow is to wake the device, send the command, wait/poll for completion, and finally receives the response from the device and does basic checks before returning to caller.

This handler supports the ATSHA and ATECC device family.

### 10.95.1 Detailed Description

CryptoAuthLib Basic API methods for Write command.

The Write command writes either one 4-byte word or a 32-byte block to one of the EEPROM zones on the device. Depending upon the value of the WriteConfig byte for a slot, the data may be required to be encrypted by the system prior to being sent to the device

#### Note

### 10.95.2 Function Documentation

### 10.95.2.1 calib\_write\_enc()

```
ATCA_STATUS calib_write_enc (
 ATCADevice device,
 uint16_t key_id,
 uint8_t block,
 const uint8_t * data,
 const uint8_t * enc_key,
 const uint16_t enc_key_id,
 const uint8_t num_in[NONCE_NUMIN_SIZE])
```

Executes the Write command, which performs an encrypted write of a 32 byte block into given slot.

The function takes clear text bytes and encrypts them for writing over the wire. Data zone must be locked and the slot configuration must be set to encrypted write for the block to be successfully written.

#### Parameters

in	<i>device</i>	Device context pointer
in	<i>key_id</i>	Slot ID to write to.
in	<i>block</i>	Index of the 32 byte block to write in the slot.
in	<i>data</i>	32 bytes of clear text data to be written to the slot
in	<i>enc_key</i>	WriteKey to encrypt with for writing
in	<i>enc_key_id</i>	The KeyID of the WriteKey
in	<i>num_in</i>	20 byte host nonce to inject into Nonce calculation

returns ATCA\_SUCCESS on success, otherwise an error code.

### 10.162.1 Detailed Description

PKCS11 Library Slot Handling.

The nomenclature here can lead to some confusion - the pkcs11 slot is not the same as a device slot. So for example each slot defined here is a specific device (most systems would have only one). The "slots" as defined by the device specification would be enumerated separately as related to specific supported mechanisms as cryptographic "objects".
